

Python Tip: f-strings

Tired of complex string formatting? Use f-strings for cleaner, faster, and more readable code.

Basic f-strings

F-strings (formatted string literals) allow you to quickly insert variables into strings. Just put an `f` before the string and use curly braces to insert variables.

```
name = "Bob"
age = 30

# Don't do this
mystring = "Hello, " + name + "! You are " + str(age) + " years old."
print(mystring)

# Do this instead
mystring = f"Hello, {name}! You are {age} years old."
print(mystring)
```

```
Hello, Bob! You are 30 years old.
Hello, Bob! You are 30 years old.
```

Formatting with Precision

You can format numbers with precision using f-strings. Simply add a colon, a number, and a letter to the variable.

```
# Format float decimal places with `f`  
pi = 3.141592653589793  
print(f"π ≈ {pi:.2f}") # 2 decimal places  
print(f"π ≈ {pi:.4f}") # 4 decimal places
```

```
π ≈ 3.14  
π ≈ 3.1416
```

```
# Format significant figures with `g`  
mass_electron = 9.10938356e-31  
print(f"m ≈ {mass_electron:.2g}") # 2 significant figures  
print(f"m ≈ {mass_electron:.4g}")
```

Wrap-Up

Now you can use f-strings to format strings with ease, precision, and readability.
